

Java for Beginners

Level 6

Mr.
Teasdale

Levels of Java coding

- 1: Syntax, laws, variables, output
- 2: Input, calculations, String manipulation
- 3: Selection (IF-ELSE)
- 4: Iteration/Loops (FOR/WHILE)
- 5: Complex algorithms
- **6: Arrays/Linked Lists**
- 7: File management
- 8: Methods
- 9: Objects and classes
- 10: Graphical user interface elements

Arrays vs Variables

Single variable

Array:

Indexes

0

1

2

3

4

Values

1

3

8

23

99

Initialising an array

One Dimensional array

Initialization `int a[] = new int [12];`

Value

1	2	3	4	5	6	7	8	9	10	11	12
---	---	---	---	---	---	---	---	---	----	----	----

Index

↑	↑	↑	↑	↑	↑	↑	↑	↑	↑	↑	↑
a[0]	a[1]	a[2]	a[3]	a[4]	a[5]	a[6]	a[7]	a[8]	a[9]	a[10]	a[11]

`System.out.print(a[5]);`

Output: 6

```
int [ ] num = new int [ 10 ];
```

↑
type of
each
element

↑
name of
array

↑
subscript
(integer or constant
expression for
number of elements.)

num

3	11	9	74	8	2	18	71	43	10
---	----	---	----	---	---	----	----	----	----

num[0] num[1] num[2] num[3] num[4] num[5] num[6] num[7] num[8] num[9]

	What could go wrong?
num [0]	always OK
num [9]	OK (given the above declaration)
num [10]	illegal (no such cell from this declaration)
num [-1]	always NO! (illegal)
num [3.5]	always NO! (illegal)

Array length

- When dealing with arrays, it is advantageous to know the number of elements contained within the array, or the array's "**length**". This length can be obtained by using the array name followed by **.length**. If an array named numbers contains 10 values, the code numbers.length will be 10.

**** You must remember** that the **length** of an array is the number of elements in the array, which is **one more than the largest subscript**.

Parallel arrays

Parallel array applications

price[]		quantity[]		revenue[]
1.99	*	56	=	111.44
4.95	*	38	=	188.10
2.99	*	42	=	125.58
14.95	*	20	=	299.00
28.95	*	17	=	492.15

Parallel arrays in Java

```
for(int index = 0; index < dogname.length; index++)  
{  
    System.out.println(dogname[index]);  
    System.out.println(round1[index]);  
    System.out.println(round2[index]);  
}
```

dogname

Wally	Skeeter	Corky	Jessie	Sadie
-------	---------	-------	--------	-------

round1

18	22	12	17	15
----	----	----	----	----

round2

20	25	16	18	17
----	----	----	----	----

****The true beauty of parallel arrays, is that each array
may be of a different data type.**

Searching an array using a *flag*

```
public class BreakBooleanDemo{
    public static void main(String[ ] args){
        int[ ] numbers = { 12, 13, 2, 33, 23, 31, 22, 6, 87, 16 };
        int key = 31;
        int i = 0;
        // set the boolean value to false until the key is found
        boolean found = false;
        for (
            ??
        )
            //When found is true, the index of the location of key will be printed.
            if (found){
                System.out.println("Found " + key + " at index " + i + ".");
            }
            else{
                System.out.println(key + "is not in this array.");
            }
        }
    }
}
```

Searching an array using a *flag*

```
public class BreakBooleanDemo{
    public static void main(String[ ] args){
        int[ ] numbers = { 12, 13, 2, 33, 23, 31, 22, 6, 87, 16 };
        int key = 31;
        int i = 0;
        // set the boolean value to false until the key is found
        boolean found = false;
        for ( i = 0; i < numbers.length; i++){
            if (numbers[ i ] == key){
                found = true;
            }
        }
        //When found is true, the index of the location of key will be printed.
        if (found){
            System.out.println("Found " + key + " at index " + i + ".");
        }
        else{
            System.out.println(key + "is not in this array.");
        }
    }
}
```

Sorting an array (*Bubble Sort*)

```
public static void BubbleSort( int [ ] num )
{
    int j;
    boolean flag = true;    // set flag to true to begin first pass
    int temp;               //holding variable

    while ( flag )
    {
        flag= false;        //set flag to false awaiting a possible swap
        for( j=0; j < num.length -1; j++ )
        {
            if ( num[ j ] < num[j+1] )    // change to > for ascending sort
            {
                temp = num[ j ];           //swap elements
                num[ j ] = num[ j+1 ];
                num[ j+1 ] = temp;
                flag = true;                //shows a swap occurred
            }
        }
    }
}
```

2D arrays

Declaring a 2D array in Java

```
int[ ][ ] arrNumbers = new int[6][5];
```

6 = number of rows (DOWN)

5 = number of columns (ACROSS)

	A	B	C	D	E
0	10	12	43	11	22
1	20	45	56	1	33
2	30	67	32	14	44
3	40	12	87	14	55
4	50	86	66	13	66
5	60	53	44	12	11

Instantiating a 2D array

A screenshot of a Java code editor window titled 'NumPad.java'. The code defines a 2D array of strings named 'keyCaps'. The array is initialized with four rows, each containing three string elements. The first row contains '7', '8', and '9'. The second row contains '4', '5', and '6'. The third row contains '1', '2', and '3'. The fourth row contains '0', 'C', and '.'. The code is as follows:

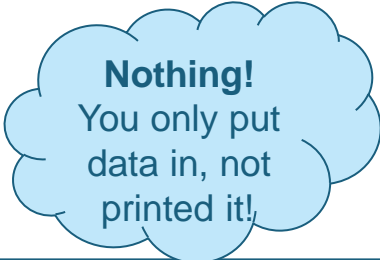

```
24  
25 String[][] keyCaps =  
26 {  
27     { "7", "8", "9" },  
28     { "4", "5", "6" },  
29     { "1", "2", "3" },  
30     { "0", "C", "." }  
31 };  
32
```

Example: Fill a 2D array with "X"

```
public class Example {  
  
    public static void main(String[] args) {  
  
        //making the 2D array  
        String[][] table = new String[5][4];  
  
        //get stuff in  
        for (int row = 0; row < 5; row++) {  
            for (int col = 0; col < 4; col++) {  
                table[row][col] = "X";  
            }  
        }  
    }  
}
```

Output

Nothing!
You only put
data in, not
printed it!

Common mistake: printing a 2D array

You can't just print the array name,
You have to print every element in the
array separately!

```
public class Example {  
  
    public static void main(String[] args) {  
  
        //making the 2D array  
        String[][] table = new String[5][4];  
  
        //get stuff in  
        for (int row = 0; row < 5; row++) {  
            for (int col = 0; col < 4; col++) {  
                table[row][col] = "X";  
            }  
        }  
  
        System.out.println(table);  
    }  
}
```

Output

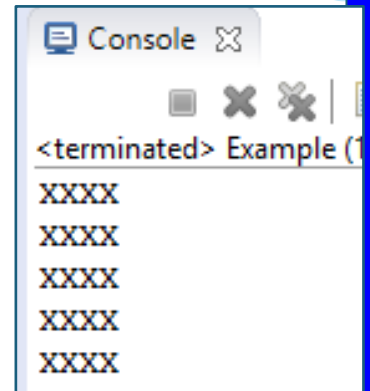

<terminated> Example (1) [Java Application] C
[[Ljava.lang.String;@2a139a55

Correct way: printing a 2D array

```
public class Example {  
  
    public static void main(String[] args) {  
  
        //making the 2D array  
        String[][] table = new String[5][4];  
  
        //get stuff in  
        for (int row = 0; row < 5; row++) {  
            for (int col = 0; col < 4; col++) {  
                table[row][col] = "X";  
            }  
        }  
        //get stuff out  
        for (int i = 0; i < 5; i++) {  
            for (int j = 0; j < 4; j++) {  
                System.out.print(table[i][j]);  
            }  
            System.out.println();  
        }  
    }  
}
```

Output

Console

<terminated> Example (1

XXXX
XXXX
XXXX
XXXX
XXXX

Common 2D array tasks

Task	Java Syntax	Examples
Declare a 2D array	<code>type[][] name</code>	<code>int[][] matrix</code> <code>Pixel[][] pixels</code>
Create a 2D array	<code>new type[nRows][nCols]</code>	<code>new int[5][8]</code> <code>new Pixel[numRows][numCols]</code>
Access an element	<code>name[row][col]</code>	<code>int value = matrix[3][2];</code> <code>Pixel pixel = pixels[r][c];</code>
Set the value of an element	<code>name[row][col] = value</code>	<code>matrix[3][2] = 8;</code> <code>pixels[r][c] = aPixel;</code>
Get the number of rows	<code>name.length</code>	<code>matrix.length</code> <code>pixels.length</code>
Get the number of columns	<code>name[0].length</code>	<code>matrix[0].length</code> <code>pixels[0].length</code>
